DNS Security Algorithm Numbers

Registration Procedure(s)

RFC Required

Reference

[RFC4034][RFC3755][RFC6014][RFC6944]

Note

The KEY, SIG, DNSKEY, RRSIG, DS, and CERT RRs use an 8-bit number used to identify the security algorithm being used.

All algorithm numbers in this registry may be used in CERT RRs. Zone signing (DNSSEC) and transaction security mechanisms (SIG(0) and TSIG) make use of particular subsets of these algorithms. Only algorithms usable for zone signing may appear in DNSKEY, RRSIG, and DS RRs. Only those usable for SIG(0) and TSIG may appear in SIG and KEY RRs.

* There has been no determination of standardization of the use of this algorithm with Transaction Security.

Available Formats

CSV

Number	Description	Mnemonic	Zone Signing	Trans. Sec.	Reference
0	Reserved				[RFC4034][RFC4398]
1	RSA/MD5 (deprecated, see 5)	RSAMD5	N	Y	[RFC3110][RFC4034]
2	Diffie-Hellman	DH	N	Y	[RFC2539][proposed standard]
3	DSA/SHA1	DSA	Y	Y	[RFC3755][proposed standard][RFC2536][proposed standard][Federal Information Processing Standards Publication (FIPS PUB) 186, Digital Signature Standard, 18 May 1994.][Federal Information Processing Standards Publication (FIPS PUB) 180-1, Secure Hash Standard, 17 April 1995. (Supersedes FIPS PUB 180 dated 11 May 1993.)]
4	Reserved				[RFC6725]
5	RSA/SHA-1	RSASHA1	Y	Y	[RFC3110][RFC4034]
6	DSA-NSEC3-SHA1	DSA-NSEC3-SHA1	Y	Y	[RFC5155][proposed standard]
7	RSASHA1-NSEC3-SHA1	RSASHA1-NSEC3-SHA1	Y	Y	[RFC5155][proposed standard]
8	RSA/SHA-256	RSASHA256	Y	*	[RFC5702][proposed standard]
9	Reserved				[RFC6725]
10	RSA/SHA-512	RSASHA512	Y	*	[RFC5702][proposed standard]
11	Reserved				[RFC6725]
12	GOST R 34.10-2001	ECC-GOST	Y	*	[RFC5933][standards track]
13	ECDSA Curve P-256 with SHA-256	ECDSAP256SHA256	Y	*	[RFC6605][standards track]
14	ECDSA Curve P-384 with SHA-384	ECDSAP384SHA384	Y	*	[RFC6605][standards track]
15-122	Unassigned				
123-251	Reserved				[RFC4034][RFC6014]

Background Questions

- Is ECC a “well supported” crypto protocol?
- Is it a reasonable candidate crypto protocol for use as the signing algorithm for the root key of the DNS?
- Is ECC as widely supported as RSA?

The ECC Question

Is there a clear signal of a set of DNS resolvers who are evidently performing DNSSEC validation using RSA-based crypto algorithms, but fail to understand ECC?

The Test Environment

We used the Google Ad network to deliver a set of DNS tests to clients to determine whether (or not) they use DNSSEC validating resolvers

We used 4 tests:

1. no DNSSEC-signature at all
2. DNSSEC signature using RSA-based algorithm
3. DNSSEC signature using broken RSA-based algorithm
4. DNSSEC signature using ECC-based algorithm

The Test Environment

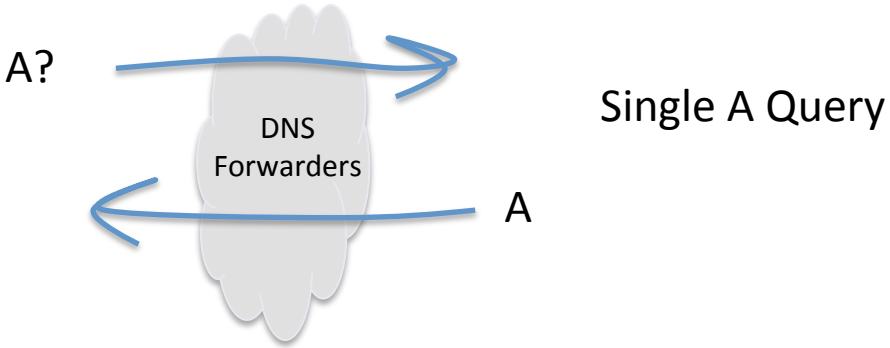
d.t10000.u2045476887.s1412035201.i5053.vne0001.4f167.z.dashnxdomain.net	Unsigned
e.t10000.u2045476887.s1412035201.i5053.vne0001.4f167.z.dotnxdomain.net	RSA Signed
f.t10000.u2045476887.s1412035201.i5053.vne0001.4f168.z.dotnxdomain.net	RSA signed (Badly)
g.t10000.u2045476887.s1412035201.i5053.vne0001.4f167.y.dotnxdomain.net	ECC-Signed

Mapped to a wildcard in the zone file

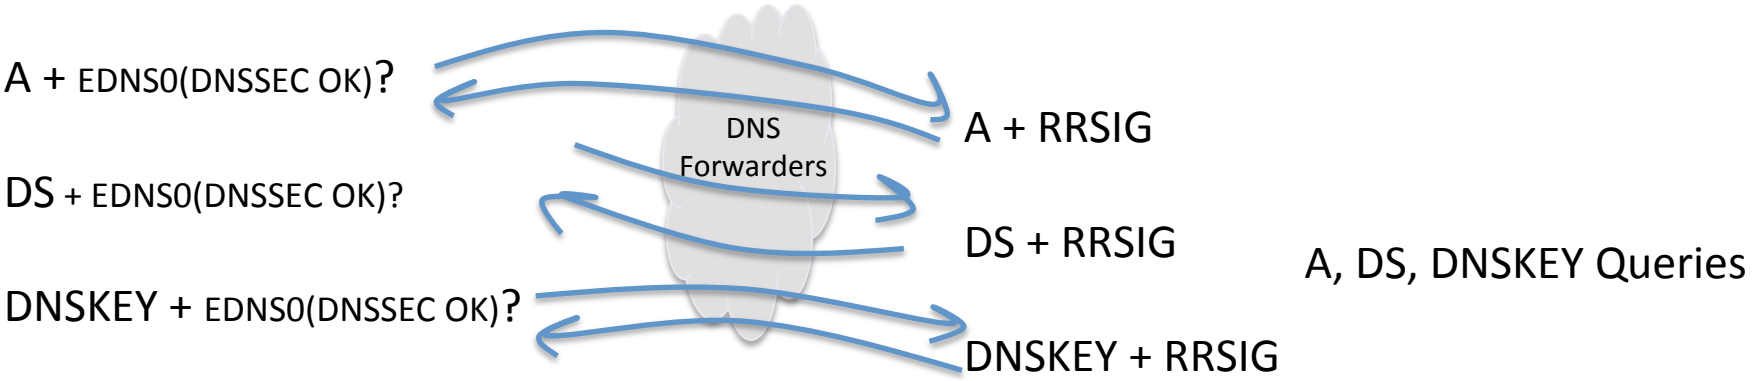
Unique Signed Zone

A Naïve View

A non-DNSSEC-validating resolver query:



A DNSSEC-Validating resolver query:



DNSSEC Validation Queries

`e.t10000.u2045476887.s1412035201.i5053.vne0001.4f167.z.dotnxdomain.net`

Query for the A resource record with EDNS0, DNSSEC-OK

query: e.t10000.u204546887.s1412035201.i5053.vne0001.4f167.z.dotnxdomain.net IN A +ED

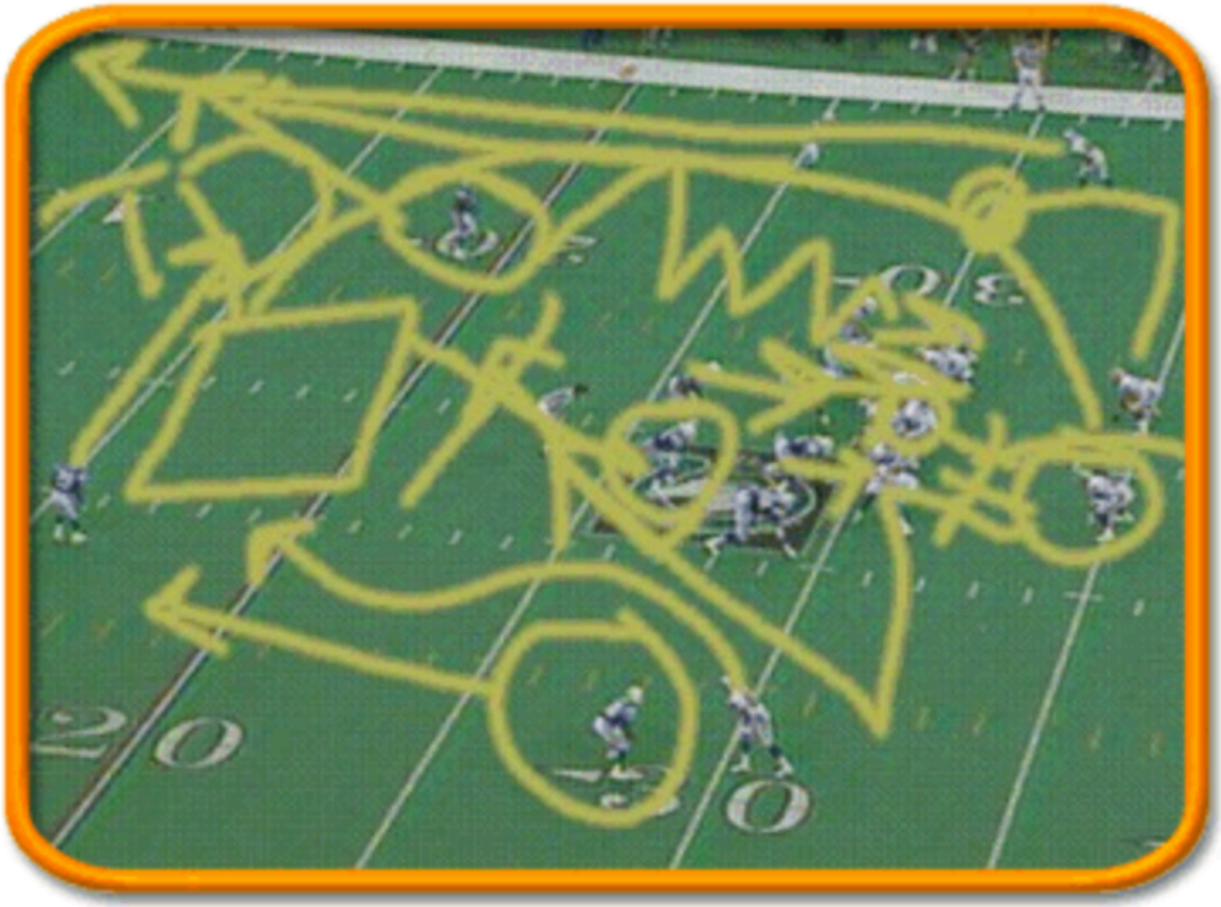
Query the parent domain for the DS resource record

query: 2f7b3.z.dotnxdomain.net): query: 4f167.z.dotnxdomain.net IN DS +ED

Query for the DNSKEY resource record

query: 2f7b3.z.dotnxdomain.net): query: 4f167.z.dotnxdomain.net IN DNSKEY +ED

What We See



The DNS is (really) messy

- The DNS is a non-deterministic environment, and the signals one sees at resolvers and servers can be incredibly confusing
- We are priming each client with a unique DNS name, and watching the DNS query traffic that appears on the only authoritative server for that name
- What we see are a variety of query patterns that reach our authoritative name server

What We See (a small random sample)

3fb0f.1410333 queries:AADD
5c323.1410361 queries:a
660e3.1410366 queries:aA

A = A + DNSSEC-OK a = A without DNSSEC-OK

Why Do We See What We See?

The DNS has no “trace” in its queries to help diagnosis

- Clients use multiple name servers, and use local timeouts to repeat the query
- Resolvers may use server farms, so that queries from a common logical resolution process may be presented to the authoritative name server from multiple resolvers, and each resolver may present only a partial set of validation queries
- Resolvers may use forwarding resolvers, and may explicitly request checking disabled to disable the forwarding resolver from performing validation itself
- Clients and resolvers have their own independent retry and abandon timers

First Approach to answering the ECC question – Statistical Inference

- A DNSSEC-aware resolver encountering a RR with an attached RRSIG that uses a known algorithm will query for DS and DNSKEY RRs

- A DNSSEC-aware resolver encountering a RR with an attached RRSIG that uses an unknown/unsupported crypto algorithm appears ***not*** to query for the DNSKEY RRs

Results

Over 22 days in September 2014 we saw:

3,773,420 experiments

937,166 experiments queried for the DNSKEY RR of a validly signed (RSA) domain (24.8%)

629,726 experiments queried for the DNSKEY RR of a validly signed (ECC) domain (16.6%)

Results

Over 22 days in September 2014 we saw:

3,773,420 experiments

937,166 experiments queried for the DNSKEY RR of a validly signed (RSA) domain (24.8%)

629,726 experiments queried for the DNSKEY RR of a validly signed (ECC) domain (16.6%)

If we assume that the DNSKEY query indicates that the resolver "recognises" the protocol, then it appears that there is a fall by 8.2% in validation when using the ECC protocol

1 in 3 experiments that fetched the DNSKEY in RSA did not fetch the ECC DNSKEY

Hmmm

- How does this relate to affected users?
- How do validating resolvers manage an unrecognised algorithm failure?

- Lets try again and look at both DNS query and web log data

DNS resolver failure modes for an unknown signing algorithm

If a DNSSEC-Validating resolver receives a response RRSIG with an unknown crypto algorithm does it:

- Immediately stop resolution and return a status code of SERVFAIL?
- Fetch the DS RR and then return a status code of SERVFAIL?
- Fetch the DS and DNSKEY RRs and then return a status code of SERVFAIL?
- Or does it abandon validation, query without the DO bit and just return the unvalidated query result?

Second Approach to answering the ECC question – DNS + WEB

Data collection: 10/9/14 – 4/10/14

552,104 clients who appear to be exclusively using RSA DNSSEC-Validating resolvers

ECC Results:

Success:	76.45%	361,698	Saw fetch of the DNSSEC RRs and the URL

Fetched the URL but appeared not to validate

Failure (1)	19.64%	108,411	Did **not** see query of DNSKEY, but fetched the URL
Failure (2)	1.47%	8,121	Saw only A queries, but fetched the URL
Failure (3)	0.84%	4,615	Saw queries with DO set and not set, fetched the URL

Did **not** fetch the URL

Failure (4)	1.07%	5,927	Saw query of the DNSSEC RRs, NOT URL
Failure (5)	0.34%	1,875	Saw query of A, DS, not DNSKEY, NOT URL
Failure (6)	0.12%	655	Saw only A queries, NOT URL
Failure (7)	0.08%	436	Saw queries with DO set and not set, NOT URL
Apparent Fail:	**23.55%**	**130,040**	

Results

- These results show that 76% of clients who appeared to exclusively use RSA DNSSEC-Validating resolvers were also seen to perform validation using ECC
- 22% of the the remaining clients fetched the object, even though the DNS queries showed that there was not a complete DNSSEC validation pass being performed
- Just 1.6% of clients did NOT fetch the URL

What?

- 23.6% ECC validation failure is very surprising
  - Don't forget that the subsection of users' resolvers being polled here already did RSA validation and appeared to correctly return SERVFAIL when the DNSSEC crypto was broken
- The fact that most of the failures result in a fetch of the URL is even more surprising
  - The expectation was that we would see far more SERVFAIL and far higher URL fail-to-fetch rates
  - It seems that the resolvers involved in this behaviour appear to be tagging the domain as "not validatable" and passing back an "insecure" outcome

Where?

ECC failure rates – the % of users in each country who use RSA DNSSEC validating resolvers, but fail to validate when the DNSSEC crypto algorithm is ECC. Top 24 countries, ranked by Observed ECC Validation failure rates

1	MN	96.82	Mongolia
2	MT	96.68	Malta
3	FI	95.75	Finland
4	AD	93.41	Andorra
5	CY	92.61	Cyprus
6	BB	90.59	Barbados
7	FJ	89.93	Fiji
8	ZA	85.94	South Africa
9	AG	84.51	Antigua and Barbuda
10	LU	83.28	Luxembourg
11	AU	79.93	Australia
12	SI	79.51	Slovenia
13	NO	78.91	Norway
14	LY	77.13	Libya
15	YE	75.81	Yemen
16	GR	69.64	Greece
17	KW	68.69	Kuwait
18	RW	66.67	Rwanda
19	BY	63.38	Belarus
20	UA	62.15	Ukraine
21	KE	60.57	Kenya
22	BA	56.35	Bosnia and Herzegovina
23	JP	56.06	Japan
24	KZ	49.50	Kazakhstan

Who?

ECC failure rates – the % of users in each AS who use RSA DNSSEC validating resolvers, but fail to validate when the DNSSEC crypto algorithm is ECC – top 25 Ases ranked by ECC failure rate

	AS	Fail Rate	Samples	AS Description
1	7155	100.00	202	WB-DEN2 - Viasat Communications Inc.,US

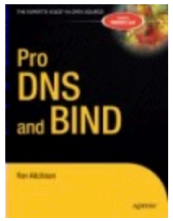
support | products | co



Contents

DNS BIND Security Statements

This section describes the **statements** available in BIND 9.x relating to security. Full list of statements.

disable-algorithms

```
disable-algorithms domain { algorithm; ...; };
disable-algorithms "." { "NSECRSASHA1"; "DH"; };
// disables NSECRSASHA1 and DH algorithms for all domains
```

disable-algorithms is only applicable to recursive name servers (full service resolvers) and allows the user to inhibit the use of one or more algorithms when validating RRSIG RR(s). The **domain** parameter defines the scope, for example, "." indicates all domains, "net" would cover all domains in the net TLD and "example.com" would cover a single domain. Multiple **disable-algorithms** statements may be included. **algorithm** may take one of the currently supported algorithms from the list RSAMD5, RSA, DH, DSA, NSEC3DSA, ECC, RSASHA1, NSEC3RSASHA1, RSASHA256, RSASHA512, ECCGOST, ECDSAP256SHA256, ECDSAP384SHA384. If the disabled algorithm is the only one supported by any signed zone then the zone will not be validated and the zone's results will be marked "insecure". This statement may only be used in a global options clause.

Is ECC a viable crypto algorithm for the Root?

These results don’t look especially promising for the use of ECC in this context

Next steps

- If we used ECC in the validation path, not at the terminal zone, would we see a similar outcome?
- What are the behaviours of resolvers when encountering an unknown crypto algorithm? Should we experiment with other algorithm code values?

Questions?
